

Theory of Reality: $R = f(T + V + P)$

This theory explains that reality is not directly experienced. Instead, the brain constructs it using time delay, speed of changes, and perception. The brain predicts outcomes and continuously corrects errors.

1. Time (T)

Time represents delay in perception. The brain predicts the present using past input.

Past	Prediction	Present

2. Velocity (V)

Velocity represents how fast changes occur. Faster changes increase prediction difficulty.

Fast change

Slow change

3. Perception (P)

Perception is the brain's internal model. It uses memory and patterns to interpret reality.

Example: Catching a Ball

When catching a ball, the brain predicts its future position. Without prediction, you would always miss.

Conclusion

Reality is a predicted model created by the brain using time delay, velocity of change, and perception.
